# Overview, Recommended Study Plan and Module Descriptions

Module No.	Module	СР
1	Dynamics, Evolution and Simulation of Geophysical Systems	12.5
2	Advanced Methods for Investigating the Earth	12.5
3	Advanced Methods in Applied Geophysics	13
4	Elective Studies: Material Physics	14 - 18
5	Elective Studies: Nonlinear Physics	14 - 18
6	Elective Studies: Geosciences	14—18
7	Interdisciplinary Studies	at least 4—8
8	Professional Specialization and Project Design	30
9	Master's Project	30

# **Recommended Study Organization**

Taken together, at least 22 CP need to be achieved in the modules "Elective Studies" and "Interdisciplinary Studies".

Degree programme	Geophysics (Master of Science)
Module	Dynamics, Evolution and Simulation of Geophysical Systems
Module number	1

1	Basic data	
Programme semester		1,2
Cred	its (CP)	12.5
Work	load (h) in total	375
Mod	ule duration	2 Semesters
Mod	ule status (M/EM)	Μ

# Aim of the module / Integration in the curriculum

This module is devoted to the dynamics and evolution of geophysical systems. While many branches of classical geophysics are concerned with determining the physical properties of the Earth, the focus of this module is on dynamical processes within the Earth system. In addition to their physical description, the module also deals with numerical modelling techniques, which are taught in the context of geophysical examples. A seminar and a colloquium allow students to gain insight into current research topics.

Teaching content

Reiteration of the basic equations of continuum mechanics and fluid dynamics; frequently used approximations of these equations; fluid flow in rotating systems; boundary layers; stably stratified flow; gravity waves; instability and turbulence in geophysical systems; convection; dynamics of the Earth's mantle; numerical algorithms for the simulation of geophysical systems; finite difference, finite volume, finite element and spectral methods; advanced methods for solving linear and non-linear systems of equations

# Learning outcomes

Students have mastered the basic principles of geophysical fluid dynamics. They are aware of the main dynamical characteristics of flows within the atmosphere, the oceans, the Earth's core and mantle. They are able to formulate the basic partial differential equations needed for the description of these geophysical systems and they have developed a profound understanding of various approaches for solving these equations numerically. The experience gained in writing a simple simulation code enables them to master more complex numerical models, to employ these for their purposes and to refine them as needed. They are aware of selected current research topics. Furthermore, they know how to give a compelling research talk.

# Aim of the module / Integration in the curriculum

Understanding and knowledge of advanced seismology and array seismic methods, reflection seismics and other geophysical methods. Ability to write a wave propagation program. Ability to analyse and interpret seismological and exploration seismic data. Overview of recent research topics.

# Teaching content

Advanced seismic concepts to investigate Earth, for example Green's functions, ambient seismic noise, monitoring, source inversion methods, array seismic methods and array design, advanced signal processing methods and mislocation vectors. Analysis and interpretation of geophysical data. Modelling of seismic and other geophysical data with different methods. Interpretation using information from petro-physics and other fields. The practical classes enhance the understanding and ability to process and analyse real data. A wave propagation model will be written. The colloquium will allow students to learn about recent advances in geophysics research.

#### Learning outcomes

The students know methods and approaches to investigate Earth's interior, they are able to extract information from complex data sets and compare to numerically generated data sets. The students have experience in error analysis and sources of errors that may arise in the analysis of geophysics data sets. The students have the ability to transfer their knowledge to other non-geophysical data sets. The understand the relevance of the acquired geophysical content for current and recent research projects.

Aim of the module / Integration in the curriculum

Procurement of advanced concepts and skills for the collection, analysis and inversion of geophysical data under special consideration of electromagnetic deep sounding (magnetotellurics).

# Teaching content

Methods for solving linear and non-linear inversion problems: deterministic and probabilistic approaches, distance methods, application of vector spaces, regularization of ill-posed problems, robust regression, gradient methods. Theory and practice of the methods of electromagnetic deep sounding and especially magnetotellurics: concepts, time series processing, analysis of transfer functions, inversion, applications in lithospheric research and exploration geophysics, interpretation. Practical application of the learned methods and procedures in an advanced field course.

# Learning outcomes

The students know the methods and procedures for the inversion of geophysical data and are familiar with the concepts of electromagnetic deep sounding methods. They are able to independently collect data and to independently apply advanced procedures and methods for data processing and inversion. They are able to implement programs to solve inverse geophysical and non-geophysical problems. Students are able to assess the validity of geophysical models of the subsurface. They know the theoretical concepts, measuring principles and application areas of electromagnetic deep sounding.

Aim of the module / Integration in the curriculum

The evolution of our society has been and is strongly affected by materials with particular properties. Steel, as an example, consisting of a mixture of iron and carbon, has allowed one to construct buildings of several hundred meters height. High purity silicon as the basic ingredient for the fabrication of electronic devices is at the heart of the digital revolution of our society and is currently partially replaced by organic-inorganic composite materials. The macroscopic properties of a material are essentially determined by defects of different dimensionality, defined as deviations from the ideal crystal structure, which constitute the so-called microstructure of a material. In the examples given above, but also beyond and in the vast majority of all materials the specific macroscopic properties of a material, like, e.g. its hardness or electrical conductivity, are directly related to the often complex and different length scale-covering microstructure and therefore refrain from being accessible by a simple consideration.

In the module, the students are introduced to the description of single- and multi-component materials and their microstructure as well as the coupling between microstructure and property. The description of defects of the crystal lattice as well as their properties and their characterization by using modern methods of materials research are discussed to provide the students with a fundamental understanding of the properties of functional materials.

#### Teaching content

Lecture materials physics: structure and crystal defects, thermodynamics and constitution, diffusion, phase transitions and reaction kinetics, mechanical properties, classes of functional materials

Laboratory course of materials physics: experimental techniques and basic physical properties of materials

Advanced lectures: choice of, e.g., atomic transport, physics of soft matter and biomaterials, semiconductor physics, polymer physics, material mechanics, nanostructured materials, numerical methods of materials physics

Learning outcomes

The students have acquired advanced knowledge in the physical concepts and methods of materials physics. They are able to contribute to pertinent current research activities.

Degree program	Geophysics (Master of Science)
Modul	Elective Studies: Nonlinear Physics
Module number	5

1	Basic data	
Program semester		1, 2
Cred	its (CP)	14 - 18
Work	load (h) in total	420 - 540
Mod	ule duration	2 semesters
Mod	ule status (M/EM)	EM

# Aim of the module / Integration in the curriculum

Nonlinear effects show up in everyday life and in nature. Particularly fascinating examples are patterns on animal fur, turbulent weather phenomena, spatio-temporal structures in the behavior of sand or optical patterns. But also, collective phenomena in biology and social sciences like the formation of swarms, neural network structures or group dynamics can be studied by using methods of nonlinear physics. In many physical, chemical, biological or also social systems which, due to energy or information flow, are kept far from thermal equilibrium, nonlinear effects lead to the formation of spatio-temporal patterns.

The goal of the module is to introduce important phenomena and the terminology of nonlinear physics in a general form and to address in depth selected topics. For this purpose, it involves both theoretical and experimental approaches. Students get a comprehensive understanding of nonlinear physics, ranging from the classification of stationary, oscillating and chaotic behavior in systems with few degrees of freedom via the spontaneous formation of structures in spatially extended systems up to nonlinear wave phenomena and turbulence, and apply it to examples in hydrodynamics, nanophysics, biophysics and optics. The module furthermore provides the opportunity to participate in the activities of the interdisciplinary Center for Nonlinear Science. Thus, in addition to many examples in the field of physics also complex systems in biology, chemistry, medicine or social sciences are addressed.

# Teaching content

The module contains theoretical and experimental topics. The focus of the studies can be more on the theoretical or the experimental side. In each combination of courses, the fundamental concepts of nonlinear physics like signatures of nonlinear and complex systems, emergence, self-organization, bifurcations, attractors or pattern formation will be addressed and specific examples of nonlinear systems will be treated. Thereby, typical nonlinear model equations and their generic properties as well as exemplary experimental systems and their applications will be discussed.

Learning outcomes

The students have developed an understanding of the fundamental concepts of nonlinear physics and are able to understand on this basis the role of nonlinearities in various physical, chemical or biological systems. They

have learned relevant methods for the theoretical and/or experimental analysis of nonlinear systems and developed skills to apply those to specific theoretical or experimental physical problems.

The students can familiarize themselves with an advanced topic in the field of nonlinear physics, prepare a talk addressed to a specific audience, present the talk and defend it in the subsequent discussion. They have the ability to contribute adequately to the scientific discussions on the subjects of the seminar talks.

Mod	ule status (M/EM)	EM

Aim of the module / Integration in the curriculum

The module provides in-depth knowledge from the field of geosciences. It enables students to set a focus in the field of geosciences. **This module is taught in German.** 

Teaching content

The contents depend on the student's election of courses.

Learning outcomes

The learning outcomes depend on the student's election of courses.

3	Structure					
Modu	ile componer	its

Aim of the module / Integration in the curriculum

This module allows students to freely choose among courses offered at WWU. This allows them to gain additional qualifications beyond those imparted by the compulsory curriculum.

# Teaching content

The chosen courses should complement the compulsory curriculum in a sensible fashion and contribute to vocational qualification. Their level must be adequate for Master's students. To guarantee these requirements the chosen courses must be approved in advance by the module representative. In addition, students must get written permission to take part in the chosen courses and exams from the respective course organizers. Appropriate forms are provided by the examination office.

Learning outcomes

Depends on the courses chosen.

Mod	ule status (M/EM)	Μ	

Aim of the module / Integration in the curriculum

Based on research-oriented special courses and the individual familiarization with the subject, the module imparts the scientific basis for the independent work on the master's thesis. The student becomes familiar with the independent acquisition of relevant information, data and literature. Special technical and numerical or mathematic skills forming the basis for the master's thesis are acquired. The cooperation with technical staff of the workshops and the institutes is trained.

Teaching content

Introduction to scientific work, elaboration of the detailed contents of the chosen scientific area, familiarization with the current research literature in the field of the planned master's thesis.

# Learning outcomes

Depending on the requirements of the chosen subject area, the student is familiar with relevant complex experimental facilities and geophysical equipment, is able to select necessary components and to procure them commercially, knows how to structure extensive calculations in such a way that the results are reliable or to implement numerical algorithms on different computer architectures.

For this module the student is already integrated in a scientific research group. By means of this integration she/he has become acquainted with efficient group work and the optimal use of informal knowledge in the close environment.

Aim of the module / Integration in the curriculum

The master's project serves for the scientific formation. In this project the student demonstrates that she/he is able to elaborate independently on a well-defined scientific problem within a research area by using scientific methods, to present the results in scientific diction in written form in the master's thesis and in oral form in the final presentation.

Teaching content

Upon agreement with the module representative.

In the research area chosen for the master's project the student elaborates under the guidance of a scientific supervisor a topical scientific problem.

Learning outcomes

In addition to the scientific contents the student has become familiar with relevant key qualifications for the work as a scientist: communication skills (also in the English language), literature research, evaluation of published data and their interpretation, accuracy in experimental work, testing strategies for newly developed programs, the will and power of endurance, writing of scientific papers, if applicable presentation of the results and exchange with other scientists at conferences, if applicable communication with suppliers and workshops.
